- This test contains 8 numbered pages, including the cover page, printed on both sides of the sheet!.
- We will use gradescope for grading, so only answers filled in at the obvious places will be used.
- Use the provided blank paper for calculations and then copy your answer here.
- Please turn off all cell phones, smartwatches, and other mobile devices. Remove all hats and headphones. Put everything in your backpack. Place your backpacks, laptops and jackets under your seat.
- You have 85 minutes to complete this exam. The exam is closed book; no computers, phones, or calculators are allowed. You may use one A4 page (front and back) of notes in addition to the provided green sheet.
- The estimated time needed for each of the 6 topics is given in parenthesis. The total estimated time is 80 minutes.
- There may be partial credit for incomplete answers; write as much of the solution as you can. We will deduct points if your solution is far more complicated than necessary. When we provide a blank, please fit your answer within the space provided.
- Do **NOT** start reading the questions/ open the exam until we tell you so!
- Unless otherwise stated, always assume a 32 bit machine for this midterm.
- 1. First Task (worth one point): Fill in you name
 Fill in your name and email on the front page and your ShanghaiTech email on top of every
 page (without @shanghaitech.edu.cn) (so write your email in total 8 times).

2.	Various	Questions	(12)	pts:	10	min))

(a) Name 6 Great Ideas in Computer Architecture.

(b) You define a short recursive MIPS procedure foo that is statically linked by two executables. Can the binary for the procedure foo be different in the two executables? Why, or why not?

(c) What is the difference between the add and addu MIPS instructions?

(c) ____

(d) Which MIPS registers are preserved over a function call (write all register names - e.g. \$m2-\$m6)?

(d) _____

(e) How many things can you represent with N bits?

(e) _____

(f) In the lecture you learned about CALL (this is the CALL regarding executing a C program on a computer). Name (each a single word) the important steps of this procedure in the right order.

form.

3.	Number Representation (16 pts; 15 min)
	Please convert the following 8-bit Signed Integers into decimal
	Explicitly write '+' and '-'.
	For example, suppose that the binary representation is 01000

For example, suppose that the binary representation is 01000001B and it is represented in Sign-Magnitude Representation, then the solution is +65D.

2	(a) If represented in Sign-Magnitude	Representation
---	--------------------------------------	----------------

Suppose the binary representation is 10000001B: _______

Suppose the binary representation is 10000000B: ______

(b) If represented in 2's Complement Representation

Suppose the binary representation is 10000001B:

Suppose the binary representation is 11111111B:

[4] (c) Suppose a is an 8-bit signed integer represented as $a_{hex} = 0$ xCB, then its binary

representation is $a_{two} =$ ______, its decimal representation is $a_{ten} =$ _____.

- (d) For an 10-bit value, two's complement integer, what are the largest AND smallest value you can represent in decimal?
- (e) Assume an 8-bit two's complement machine on which all operators are performed on 8-bit registers. Answer the results of the following operations in hexadecimal. Assume that subtraction is done with SUBU and addition is done with ADDU.

5

5

- 4. C programming I (14 pts; 14 min)
 - (a) What is the value of **s** in the following code? If possible, also provide the actual number in decimal.

```
unsigned int t[] = \{0, 1, 2, 3, 4, 5\};
unsigned int s = sizeof(t);
```

- (I) The length of the **t** array.
- (II) The number of bytes in the t array.
- (III) The number of bytes in one unsigned int.
- (IV) The number of bytes in an unsigned int pointer.
- (V) Nothing: an error will be produced.

(a)

(b) What does the following method do?

```
char * func(char *f, char y) {
  char *h = f;
  for(h = f; *h != y && *h) {
    h++;
    if(*h) {
     *h = 0;
     h++;
    }
  }
  return h;
}
```

- (I) It returns a pointer to the first location of y in f.
- (II) It splits **f** at the first occurrence of **y** and then returns a pointer for the remaining string.
- (III) It finds the last location of y in f, zeros put that location, and then returns a pointer to the next location.
- (IV) It zeros out **f** until it finds **y**. It then returns a pointer to the location of **y** in **f**.
- (V) Nothing; it cannot be complied.

(b)

(c) The **%s** format specifier takes in a **char*** and prints until it finds a null character. What do the following two lines of code print?

```
char *s = "uncharacteristic";
printf("%s", s+s[7]-s[6]);
```

(c)

9

- 5. C programming II (18 pts; 10 min)
 - (a) Given the code below:

```
int a;
const char * b;
int foo(short c) {
   char d;
   static int * e = malloc(sizeof(int));
}
int main() {
   int f;
   foo(3);
}
```

Name all areas of memory that are used by the program:

(a) _____

At which area of the memory are the following variables stored:

a: b: c: d: e: f:

- (b) 1. When passing parameters to functions, what is the difference between **call by value** and **call by reference**?
 - 2. What is the default function call method in (I) MIPS and (II) \mathbb{C} ?
 - 3. How can we achieve the other call method?

6. Bits and Pieces (17 pts; 15min)

Read the following MIPS assembly code and answer the following questions. Your answers should be as concise as possible.

```
halo:
 #BEGIN
 addiu $v0, $0, 0
 addiu $s0, $0, 0
 addiu $s1, $0, 0
 beg $a0, $0, finish_the_fight
 addiu $s0, $a0, 0
 addiu $s1, $0, 1
 andi $t0, $s0, 1
new_mombasa:
 bne $t0, $0, finish_the_fight
 srl $s0, $s0, 1
 sll $s1, $s1, 1
 andi $t0, $s0, 1
 j new_mombasa
finish_the_fight:
 addiu $v0, $s1, 0
 #END
 jr $ra
```

(a) Briefly explain what halo returns with respect to the input.

(b) Try to implement the function in C as efficient and concise as possible. (The space given below is more than enough.)

(c) We've broken some assembly language calling conventions with the code above. Write the code that should be inserted at the positions of #BEGIN and #END to correct it.

At #BEGIN:

At **#END**:

7. MIPS & Branch-if-equal instruction (22pts; 16 min)

10

(a) True/False: circle the correct answer (2 pts each)

T F 1. Branch instructions in MIPS can only jump forward 32768 and backward 32767 instructions.

T F 2. A carry-out at the most significant bit after an addition of two signed numbers always indicates overflow.

T F 3. I-type instructions always cause pipeline bubbles.

T F 4. If we only have three parameters to send to a non-recursive function, then we can use registers and don't need to use the stack.

T F 5. Every location in the text segment is accessible from a single branch statement.

6

- (b) Consider a hypothetical branch-if-equal instruction that is 32 bits long:
 - 6 bits are used to encode the opcode
 - 6 bits are used to encode one register number
 - 6 bits are used to encode another register number
 - 14 bits are used to encode an offset that will be added to the program counter (PC) if the branch ends up being taken, and a new instruction address is required. (The number is not in 2's complement form, and all 14 bits can encode a constant.)

Thus, the instruction syntax might be: BEQ R12, R11, X

- If R12==R11, the PC will be set to PC+X instead of PC+4.

Given this instruction, is the code shown in the table below valid? Why or why not? Explain in detail.

Address	Instruction
5000	•••
5004	BEQ R12, R11, X
5008	Add R1, R2, R3
•••	
X: 21256	Sub R1, R2, R3

(c) Instruction Format: Translate the assembly into machine code and vice versa (use named registers - not register numbers).

Instruction	Code (hex)
lb \$t3, 7(\$s5)	
	0x00128a00
